REDWOOD RISK · FACTSET DATA-EXTRACTION CALL

Final spec walkthrough before the massive run

A go-through-one-by-one agenda. Goal: by end of call we have a yes/no on every Critical and Confirmation item, and FactSet sends a short test pull with the remaining fixes applied. Once that test pull passes our integrity checks, you green-light the full extraction including the 15+ new accounts.

Drafted 2026-04-27 Last audited against latest_data.json (EM strategy) Print-to-PDF works (Cmd+P)

> **How to run the call:** walk through items in order. Items already shipped in current data are struck through for confirmation only. Outstanding items have OPEN badges; partials have PARTIAL. Confirm what shipped, address what's outstanding.

AUDIT SUMMARY — WHAT'S ALREADY IN THE LATEST DATA

✓	A2	**Per-stock factor data** — all 16 factors (12 style + Market + Industry + Country + Currency) populated in every holding row. Big unlock now in hand.
✓	A5	**Group tables — all rows** — sector + country bench sums = 100%. All 11 GICS sectors present.
✓	F7	**Granular per-currency / industry / country attribution** — 141 keys in snap_attrib.
✓	–	**Per-holding sector / region / country / industry columns** shipped on Security rows.
✓	–	**Compounded Factor Return** column populated.
✓	–	**Section column + date columns** shipped.
◐	A1	**Holdings completeness** — current EM file has 40 portfolio + 1030 benchmark holdings of 1217 total. Massive improvement (was 17/41 before). Verify across all 7 strategies.
◐	A3	**RiskM Active Exposure** — populated for 12 of 17 factors. Missing: Dividend Yield, Earnings Yield, Liquidity, Market Sensitivity, Volatility. Could be header alignment or a model-vs-universe issue (see B9).
◐	A4	**Per-factor TE %** — 17/17 factors have a value, but 7 are still synthesized on our side. Need real values from FactSet.
◐	C1	**Brinson per-holding period return** — `r` field populated on 735/1217 holdings. Needs confirmation that this means what we think.

RE-FLAG	**Benchmark P/E and P/B** — was confirmed at the prior call, but rows exist with NULL values. Did this slip?
A6, A7, B1–B11, C2–C9, D1–D5	Still outstanding (forward-looking confirmations + additions + logistics).

A Critical — must resolve before the massive run

If any of these aren't fixed, the dashboard ships with gaps the PMs will see immediately.

A1 Every weekly file must contain ALL holdings, not just a partial sample

CRITICAL PARTIAL

WHAT WE NEED	Every week's data block needs to list every stock the portfolio owns AND every stock in the benchmark that's a meaningful risk contributor (a benchmark-only position above 0.5% weight, OR contributing more than 1% of tracking error).
WHY IT MATTERS	Today most strategies show only 19–50% of their actual holdings. Worst case: GSC has 9 of its 50 holdings — 81% missing. Every drill-down, every "which stock is driving Industrials' risk?" question hits a wall. Sector-table totals don't reconcile against summed-up holding totals (IDM Industrials: 8.3% from holdings, 25.6% in the sector table).
NOW	**Greatly improved.** Latest EM file: 40 portfolio + 1030 benchmark = 1070 holdings of 1217 total in the section. Coverage looks complete for EM. **Confirm at call:** does this hold across the other 6 strategies (IDM, ACWI, IOP, GSC, ISC, SCG)?
DONE WHEN	Counting Security rows for any strategy = portfolio-holding count + the benchmark-overlap holdings passing the materiality filter. Both numbers match the strategy's stated holdings count in its Summary section.

A2 ~~Add per-stock factor data on the Security rows~~

CRITICAL RESOLVED

WHAT WE NEED

For each holding, two new column blocks per weekly snapshot:

1. Factor TE contribution per holding — how each stock's total tracking error (%T) splits across the 12 style factors plus Market, Industry, Country, Currency. Sums to the stock's %T.

2. Raw factor exposures (Axioma z-scores) per holding — the loadings on those same factors.

If file size allows, the wide version is preferable: every individual industry, every individual country, every individual currency listed as separate columns. If not, the 12 styles + 4 aggregates is the floor.

WHY IT MATTERS

This is the single biggest unlock in the dashboard. Today we can see "TSMC contributes 6.9% to TE, 3.6% of which is stock-specific" — but we cannot say WHICH factors that other 3.3% flows through. With this data: "adding TSMC would raise our Volatility exposure by X" becomes answerable. Sector / country / region tables can show factor breakdowns rolled up from holdings without us needing to ask FactSet for parallel group-level fields.

NOW

Shipped. Every holding row carries factor_contr with all 16 factors populated: 12 style (Mom · Val · Gro · Prof · Size · Vol · Yield · Earnings Yield · Liquidity · Leverage · Mkt Sens · FX Sens) + 4 macro (Market · Industry · Country · Currency). Dashboard tiles already use it.

FOR CALL

Confirm this is the locked-in format for the massive run + 20-yr history (i.e., none of these 16 columns will get renamed or dropped).

A3 RiskM section: column headers must match the data underneath them

CRITICAL PARTIAL

WHAT WE NEED	In the RiskM section of the new sample, several cells contain numeric values in column positions where the header label says something else (e.g., a date-label column position holding a TE value). Some factor-name columns are missing entirely. Headers and cell content need to align unambiguously.
WHY IT MATTERS	Our parser uses the text of the header row to identify the per-factor "% of Variance" and "Active Exposure" blocks. When those anchors are missing, all factor exposures and all factor TE contributions in the parsed JSON come out null. We've worked around this, but it's fragile and the next format change could quietly break it again.
NOW	**Improved but not done.** Latest EM file: 12 of 17 factors have Active Exposure populated. Still null: **Dividend Yield, Earnings Yield, Liquidity, Market Sensitivity, Volatility**. These are STYLE factors, not the macro aggregates. Two possibilities: (a) header still misaligned for these specific 5; (b) Axioma model genuinely doesn't estimate these for EM (see B9). FactSet should clarify which.
FOR CALL	Either fix the headers (if alignment) or document the missing-by-design pattern (if model). Either way, the dashboard needs to know whether to show "—" or wait for data.

A4 Per-factor TE contribution — populated for every factor, not just some

CRITICAL PARTIAL

WHAT WE NEED	For every factor, ship the actual percentage of total tracking error attributable to it. Today this is null on Growth and most other factors; only a handful (Momentum, Volatility) have it populated.
WHY IT MATTERS	The dashboard previously synthesized this number where missing — multiplying active exposure × factor stdev and normalizing the result. The user banned that approach after a synthesized 15.1% Size contribution looked plausible but was actually fabricated. Hard rule going forward: every visible number traces to FactSet or shows as missing. So we need this field populated for real, not approximated.
NOW	**Partial.** All 17 factors now have a value (f.c populated), but 7 of them are still synthesized on our side (`_c_synth=true`). The dashboard still shows the "ᵉ" derivation marker on those 7. We need real source values for them, not synthesized ones.
FOR CALL	Confirm whether FactSet is shipping all 17, or only some. If only some, surface which ones and why — we'll show "—" instead of synthesizing per anti-fabrication policy.

A5 ~~Group tables (Sectors, Countries, Industries, Regions, Style Groups) — include every group, even when port weight is zero~~

CRITICAL RESOLVED

WHAT WE NEED

Today, group tables exclude rows where the portfolio owns nothing. That hides active underweights. If we're 0% in Energy and the benchmark is 3.8% Energy, we want to see a row showing W=0, BW=3.8, AW=−3.8 — not a missing row.

WHY IT MATTERS

Active underweights are exactly what a risk dashboard exists to show. Hidden zero-weight rows mean the PM can't see "we're 7% underweight Industrials" if Industrials happens to also be a 0% portfolio position. Benchmark coverage today sums to 60–95% across strategies instead of 100% because of this hiding.

NOW

Shipped. Latest EM file: 11 GICS sectors all present, sector benchmark sum = 100.0%. 27 countries, country benchmark sum = 100.0%. Group tables look complete.

FOR CALL

Confirm same fix applied to: Industry table, Region table, RWOOD style groups (8 groups). Confirm holds across all 7 strategies.

A6 "Overall" rank table — quintile groupings are mis-bucketed

HIGH OPEN

WHAT WE NEED	In the rank tables, holdings should be bucketed by their quintile rank. Q1 should contain only stocks with rank=1, Q2 only rank=2, etc. The sub-rank tables (REV, VAL, QUAL) do this correctly — Q1 weighted-avg comes out exactly 1.00, Q2 exactly 2.00, and so on. The "Overall" table doesn't — it shows 1.78 for Q1, 2.43 for Q3, 2.91 for Q5. That means stocks with different Overall ranks are being mixed into the same group.
WHY IT MATTERS	The dashboard's Spotlight tile uses these quintile averages to highlight quality concentrations. When the buckets don't actually represent their named rank, the table reports nonsense — Q1 ("best stocks") shows an average rank of 1.78 which means it includes stocks ranked 2 and 3 too.
TODAY	Ticker rows appear inside quintile groups in the Overall table (IDM has "2875" as a row alongside Q1-Q5; ACWI has AMZN, ALAB, BWXT, EXEL, NU; GSC has only 3 of 5 quintile rows). REV/VAL/QUAL tables are clean.
DONE WHEN	Overall table shows 5 quintile rows only (no individual tickers), and OVER_WAvg = 1.00 in Q1, 2.00 in Q2, ... 5.00 in Q5 — exact integers, just like the sub-rank tables.

A7 Quote all string fields — security names with commas are silently corrupting rows

HIGH OPEN

WHAT WE NEED	Every text field in the CSV (security names especially) wrapped in double quotes. So "ABC Corp., Ltd." stays in one column instead of splitting at the embedded comma.
WHY IT MATTERS	Currently, names like "Pathward Financial, Inc." split into multiple columns. The weight columns shift by one, the position becomes effectively lost from the dataset, and dashboard totals quietly under-count. We caught one but there are likely others.
TODAY	Confirmed at least one name-comma case (CASH = Pathward Financial, Inc.) corrupts that row's columns.
DONE WHEN	Searching the file for any text-field comma returns zero off-by-one column shifts. All security names are quoted.

B Confirmations — yes/no questions that need answers in writing

These don't necessarily change the file format; they confirm how things will behave so we can plan around them.

B1 15+ new accounts coming in the massive run — same file structure?

CONFIRMATION

QUESTION	Will all 15+ accounts ship in a single file with an ACCT column distinguishing them, OR each in a separate file with identical schema? Will the column structure be identical across all of them, including custom-blended-benchmark accounts and any fund-of-funds?
WHY WE ASK	Our parser is header-driven and adapts to column-count differences automatically — but only within known section types. If a fund-of-funds (sleeve-of-sleeves) needs a different column count, we want to know upfront so we don't assume it's a corrupted file.
GOOD ANSWER LOOKS LIKE	"All 15+ ship in one concatenated file with consistent column structure. Custom blended benchmarks are flagged in the BENCHMARK column. No fund-of-fund schemas in this batch."

B2 20-year history — current factor names + current GICS classifications applied retroactively?

CONFIRMATION

QUESTION

Going back 20 years (~2006), the Axioma model has shipped multiple versions and several factors have been renamed over time (e.g., "Medium-Term Momentum" used to be written differently). GICS has also reclassified — Retailing became Consumer Discretionary Distribution & Retail; Media became Media & Entertainment; Pharmaceuticals split.

For the long history pull, will FactSet apply the current names retroactively across the full series, OR will historical periods carry their period-correct names?

WHY WE ASK

The dashboard tracks each factor and each industry as a single time-series. If a factor renames mid-history, the chart breaks into two unrelated series. Same for an industry that splits. Retroactive consistent naming is what the dashboard needs.

GOOD ANSWER LOOKS LIKE

"Yes, current factor names and current GICS taxonomy applied retroactively across the full 20-year series. Pre-split categories already merged into their current equivalents."

B3 After the massive run, how do ongoing weekly updates land?

CONFIRMATION

QUESTION

Once the 20-year baseline lands, future weekly pulls should APPEND to it. Two options:

Option 1 — append-only: each new week is a small file containing just that week's data. We append to our local store.

Option 2 — full re-pull: each weekly file contains the full history again. We replace our local store every week.

Which is the plan? And: SFTP / S3 / API / email? What day of week, what time?

WHY WE ASK

RR's storage architecture assumes append-only — full re-pulls would re-run the entire pipeline every week, defeating the purpose of historical snapshots. Also: for a confidence check that data isn't drifting, we need to know exactly what each weekly delivery contains.

GOOD ANSWER LOOKS LIKE

"Append-only weekly delivery via SFTP, posted Tuesday 7am ET, containing only the new week's data with identical schema to the historical baseline. Files are named [date]_[batch].csv."

B4 Date convention — what day does each weekly snapshot represent?

CONFIRMATION

QUESTION

Each weekly snapshot — does the date column refer to Friday's close, Monday's open, T+1, end-of-day, intraday? Just confirming the convention so the dashboard's date labels mean what we think.

WHY WE ASK

If we tell a PM "this is your 4/19 snapshot" and they pull a separate 4/19 trade-blotter that turns out to be Monday's pre-market state, those numbers won't reconcile. Better to confirm now.

GOOD ANSWER LOOKS LIKE

"Date column = Friday close, T+1 priced. We use last available close for any non-trading Friday."

B5 For ADRs and dual-listings, what does "Country" and "Currency" mean exactly?

CONFIRMATION

QUESTION	For an EM stock like a TSMC ADR listed on NYSE in USD: country-of-incorporation = Taiwan, country-of-listing = US, country-of-risk = Taiwan, currency-of-listing = USD, currency-of-risk = TWD. Today's Security section has Country and Currency columns — which of these conventions do they follow?
WHY WE ASK	For risk attribution, country-of-risk is what matters (TSMC's risk is tied to Taiwan even if it trades in USD on NYSE). For currency exposure, currency-of-risk is what hedging decisions reference. The wrong convention makes country and currency tiles useless for EM and ACWIxUS strategies.
GOOD ANSWER LOOKS LIKE	"Country column = country-of-risk (where the business operates). Currency column = currency-of-revenue / functional currency. Both fields independent of listing venue."

B6 Section anchors — text labels in the file that tell our parser where one section ends and the next begins — will those stay stable?

CONFIRMATION

QUESTION

Our parser identifies sections by looking for known text patterns ("RiskM", "Security", "Sector Weights", "% of Variance", "Active Exposure"). If those exact strings change in any future export — even subtly (added space, different capitalization, renamed) — the parser will silently drop that section and fields will go null.

Will those anchor strings remain bit-identical across:
1. The 15+ new accounts
2. The 20-year history
3. Future weekly updates

If a section needs to rename, can FactSet give us a heads-up email so we can update the parser before the change ships?

WHY WE ASK

We've already had one parser-drift incident (April 2026) where 4 different parser code paths each interpreted column 15 differently after a format change, producing wacky on-screen numbers (like 60% idiosyncratic risk where the truth was 49%). Anchor stability is a guard against that happening again.

GOOD ANSWER LOOKS LIKE

"Anchor strings are stable across all three dimensions. We'll email you in advance if any section name needs to change."

B7 [Cash], @NA, [Unassigned] — what do these special row labels mean?

CONFIRMATION

QUESTION

Confirm:
- [Cash] = portfolio's cash allocation (assumed)
- @NA = holdings that couldn't be classified into a grouping dimension (sector, country)?
- [Unassigned] = same as @NA, or different concept?
- Are @NA / [Unassigned] weights INCLUDED in the named-group totals (so a sector's W is final), or do they sit OUTSIDE all named groups (so totals don't sum to 100%)?

WHY WE ASK

If we double-count an @NA position (counting it once in [Unassigned] and once again in some sector), portfolio totals exceed 100%. If we leave it out, they undershoot. Need to know which.

GOOD ANSWER LOOKS LIKE

"[Cash] = cash. @NA = could not classify the security; not included in named-group totals (so weights don't sum to exactly 100, the @NA bucket carries the residual). [Unassigned] is the same concept for groups that don't have a name yet (or for cash for purposes of style classification)."

B8 Cumulative Factor Impact — compounded daily or weekly?

CONFIRMATION

QUESTION

In the 18 Style Snapshot section, the Cumulative Factor Impact column — is it computed by chaining the underlying daily factor returns through every trading day from start, OR by chaining the weekly figures together (1+w1)(1+w2)...(1+wN) - 1?

WHY WE ASK

PMs sometimes want to see attribution for arbitrary sub-periods (e.g., 2020-2022 only). If cumulative is computed daily and we try to reconstruct the sub-period from weekly figures, we'll have small rounding drift — not a deal-breaker but worth knowing the magnitude over a 20-year window.

GOOD ANSWER LOOKS LIKE

"Cumulative is computed by daily compounding. You can reconstruct sub-periods from weekly figures with a typical drift of ~1bp over 5 years."

B9 Why are some Axioma factors blank for some strategies?

CONFIRMATION

QUESTION

Across all strategies, certain factors have empty cells in RiskM. The pattern is systematic, not random:

- Empty Active Exposure: Earnings Yield, FX Sensitivity, Market Sensitivity, Momentum (6 of 7 strategies)
- Empty % of Variance: Leverage, Liquidity, Profitability, Volatility (same 6 strategies)

Is this a model-vs-universe phenomenon (some Axioma factors not estimated for certain regions, e.g., EM)? Or a report-config issue we can flip?

WHY WE ASK

If it's a model thing, the dashboard should show "—" with a tooltip explaining the factor isn't available for this universe. If it's a config switch, we want it flipped.

GOOD ANSWER LOOKS LIKE

"It's the model — Axioma's medium-cap EM model omits Earnings Yield and Momentum because the historical fit was weak in EM. Other gaps are config; we can flip those on."

B10 For new IPOs and illiquid OTC names — what do empty factor cells mean?

CONFIRMATION

QUESTION

A stock that IPO'd a month ago, or an illiquid OTC name without enough trading history, won't have an Axioma exposure. When that happens, what does the cell show? Blank? Zero? Some sentinel value? Need to be able to distinguish "intentionally zero" from "data not available".

WHY WE ASK

If "data not available" comes through as 0, the dashboard's risk math treats the position as risk-free, which is dangerous. If it comes through as blank, our parser knows to flag it and the dashboard shows a "—" instead.

GOOD ANSWER LOOKS LIKE

"For securities without sufficient history, all factor exposure cells are left blank (empty string). The Spotlight ranks are populated separately and may still be present."

B11 Decimal precision — how many digits, are values rounded?

CONFIRMATION

QUESTION	Weights, returns, and TE contributions — what decimal precision is exported? Are values rounded at write-time, or pass-through from the source?
WHY WE ASK	For very small bench-only positions (a 0.04% TE contribution), we want to know if it's truly 0.04% or if it could be anything from 0.035 to 0.045 due to rounding. Affects how we sum many small contributions and reconcile against the portfolio total.
GOOD ANSWER LOOKS LIKE	"Weights to 2dp, returns and TE contributions to 4dp, both rounded at export. Source is higher precision but we don't expose it in CSV."

C Additions — only if straightforward to include

If easy to add, transformative. If not, can wait. Order = priority.

C1 Brinson attribution inputs — sector-level returns

HIGH PARTIAL

WHAT WE'D ADD

Per period (weekly), three new fields:

1. `sector_port_return` — total return contribution of the portfolio's holdings in each sector
2. `sector_bench_return` — same for the benchmark's holdings
3. `bench_total_return` — the benchmark's total period return (one number)

Easier alternative: just add a single `PERIOD_RETURN` column on each holding row. We can aggregate up to sector / country / industry / group on our side.

WHY IT MATTERS

Brinson is the standard PM-facing attribution view: "your alpha came from being right on Sector Allocation, Wrong on Stock Selection within Tech". The dashboard has a slot for it but no source data. Single biggest net-new analytical capability if shipped.

NOW

Maybe partial. Holdings carry a per-row `r` field populated on 735 of 1217 rows in the latest EM file. Not sure if this is the period return for Brinson or something else. Confirm what `r` represents and whether it's intended as the Brinson input.

C2 18 Style Snapshot — add a "% of Variance" column

HIGH

WHAT WE'D ADD

One new column on every row of the 18 Style Snapshot section: % of Variance (TE contribution).

WHY IT MATTERS

Today, "which specific industry contributes the most to risk?" requires breaking out RiskM into thousands of new rows (one per industry × period × strategy). Adding ONE extra column on the existing snapshot rows accomplishes the same thing with negligible file growth, and puts return attribution and risk contribution side by side.

C3 Sector / Country / Industry historical fields — %T, %S, W, BW per period

MEDIUM OPEN

WHAT WE'D ADD	Per group, per weekly period: the same four fields the holding-level data has — total TE %, stock-specific TE %, portfolio weight, benchmark weight.
WHY IT MATTERS	The dashboard has a Trend column inside every group table that's supposed to show how each sector's risk contribution evolved over time. Today, sector-level historical %T isn't shipped, so the column shows a static current-state indicator only. With this data, the column lights up with full multi-week trends.
NOW	**Empty.** hist.sec is empty in the parsed JSON — no per-sector weekly history.

C4 Top-10 fundamental metrics — port + bench averages

MEDIUM OPEN

WHAT WE'D ADD

Same vertical Portfolio Characteristics format as today's section. Adds 10 more rows:

1. Forward P/E (NTM)
2. EV/EBITDA
3. Price/Sales
4. Revenue Growth 1Y
5. ROIC
6. Net Debt/EBITDA
7. Total Return 1Y
8. Excess Return vs Benchmark 1Y
9. Gross Margin
10. EPS Growth NTM

Both portfolio and benchmark weighted-average values (same format as Market Cap, ROE, etc. today).

WHY IT MATTERS

Transforms the Characteristics tile from 8 metrics to 18 — covers forward valuation, capital efficiency, leverage quality, return-vs-bench. The next 36 metrics on our list are nice-to-have; these 10 are the ones every PM I've talked to expects.

C5 Hit rate / batting average

NICE

WHAT WE'D ADD

A single number per period: percentage of active positions that contributed positively to relative return. Standard summary stat.

WHY IT MATTERS

Common PM scorecard metric. We have a slot in the dashboard but no data behind it.

C6 Trailing returns at the strategy level — 1M / 3M / 6M / 1Y / 3Y / 5Y / since-inception

NICE

WHAT WE'D ADD

Per strategy, per snapshot: 7 trailing-period total returns for portfolio, benchmark, and active. Standard performance grid.

WHY IT MATTERS

Today we have weekly/cumulative factor impact, but no clean strategy-level trailing return numbers. Common ask from PMs reviewing the dashboard.

C7 Currency hedging exposure for hedged share-classes

NICE

WHAT WE'D ADD

For any of the 15+ new accounts that run with currency hedging, expose the hedge ratio per currency or net hedged exposure. Simple summary fields would do.

WHY IT MATTERS

Hedged-share-class strategies have a meaningful chunk of their risk profile in currency overlay. Today the dashboard has no view into that.

C8 Holdings turnover per period

NICE

WHAT WE'D ADD

Per strategy, per period: the percentage of portfolio NAV that traded that period. A direct turnover number.

WHY IT MATTERS

Today, "how much did the portfolio change last week?" requires diffing two consecutive snapshots. Direct turnover would be cleaner and let us answer "was this past month's alpha mostly from new positions or maintained ones?"

C9 Daily-frequency data option for the most recent month

NICE

WHAT WE'D ADD

For the last 30 days, an optional daily-frequency file alongside the weekly bulk. Doesn't need to be retroactive; just current.

WHY IT MATTERS

Improves attribution accuracy on intra-week events — earnings days, tariff announcements, central-bank moves. PMs sometimes ask "what did Tuesday's tariff news do to my exposures by Wednesday?" — daily resolution answers that; weekly doesn't.

D Logistics — confirm before signing off

D1 Test pull first, before the full massive run

HIGH

ASK

Before committing to the full 15+ account, 20-year extraction, ship a SHORT verification file:

- 1–2 weeks of data only
- 2–3 representative strategies (one developed, one EM, one small-cap)
- All Section A fixes applied
- A schema document listing every section, column, units, and edge cases

We'll run our integrity-check pipeline against it (~5 minutes) and confirm everything is right before you commit compute to the bulk extraction.

WHY IT MATTERS

Catches column-shift, anchor-drift, and rounding issues before they get baked into a multi-hour extraction. Saves both teams time on the back-end.

D2 Delivery channel + schedule for ongoing weekly updates

CONFIRMATION

ASK

Confirm delivery mechanism for: (a) the test pull, (b) the massive run, (c) ongoing weeklies. SFTP / S3 bucket / API endpoint / email / shared drive? Day-of-week and time-of-day for the recurring weekly?

D3 Schema document alongside the test pull

HIGH

ASK

When you ship the next sample, include a brief schema doc that lists every section, every column, the value type, units, and any edge-case behavior. Living doc both teams reference. Avoids "what does column 47 mean?" debates later.

WHY IT MATTERS

Makes Section B confirmations re-checkable in the future and creates a single source of truth when the inevitable "did the format change?" question comes up months later.

D4 Backwards-compatibility commitment

HIGH

ASK

Once a column ships in a delivered file, it doesn't get removed or renamed in future pulls without 30 days' notice. We can absorb additions any time. Removals or renames break the parser silently and cost a day or two to diagnose.

D5 Account code mapping for the 15+ new accounts

HIGH

ASK

As soon as the new account list is finalized, share a mapping table: account code → strategy name → benchmark. We pre-register each in the dashboard's strategy-mapping config and update our reference data so they're recognized on day one.

ALREADY CONFIRMED FROM PRIOR CALLS — AUDIT AGAINST LATEST DATA

✓ ● **RE-FLAG** **Benchmark P/E and P/B** — was confirmed at the prior call, but in the latest EM file `b: null` on both Price/Earnings and Price/Book characteristic rows. Did this slip through?

✓ ✓ **Date columns added to each table**

✓ ✓ **Compounded Factor Return populated** (was blank before)

✓ ✓ **Overall Rank extra column removed** from holdings sections

✓ ✓ **Section column with explicit labels** (RiskM, Security, etc.)

✓ ✓ **Per-holding grouping columns** (Sector / Region / Country / Industry / Subgroup) on Security rows

Bench P/E + P/B regression: if it didn't ship despite being committed, this is the kind of silent backslide that motivates the backwards-compat ask in §D4. Worth raising early in the call.

Suggested call opener

> *"We've parsed and validated against the latest sample — most of it works, but a few specific things are blocking the dashboard from being PM-ready. I'd love to walk through the agenda I sent: Section A is must-resolve, Section B is yes/no confirmations, Section C is additions only if they're straightforward. The goal is to come out of this call aligned on a short test pull, then I verify on my side, then you green-light the full 15+ account run. Let's start at A1."*

Post-call next steps (your side)

- [ ] Receive the short verification sample from FactSet
- [ ] Run `./load_data.sh <sample>.csv` — confirm the integrity-check console message reads ✓
- [ ] Spot-check each Section A item against its Done-when criterion
- [ ] Verify Section B confirmations match what shipped in Section A
- [ ] Audit a representative sample of cardSectors / cardCountry / cardRiskByDim against the new fields
- [ ] Mark FACTSET_FEEDBACK.md F-items as Closed/Resolved with the sample-file SHA
- [ ] Green-light the massive 15+ account run
